

toString () Method:

when we print a class
Student Student1 = new Student;
like this
System.out.println (Student1);

it calls its toString method.

By default it is already written but we
can override it in that class.

Packages :

Simple Definition:

"They are basically
containers for classes. They keep classes
compartmentalised"

~~A package will allow you to~~

In simple terms they are just folders
but in java we actually have a
structure like

OOP: Intro

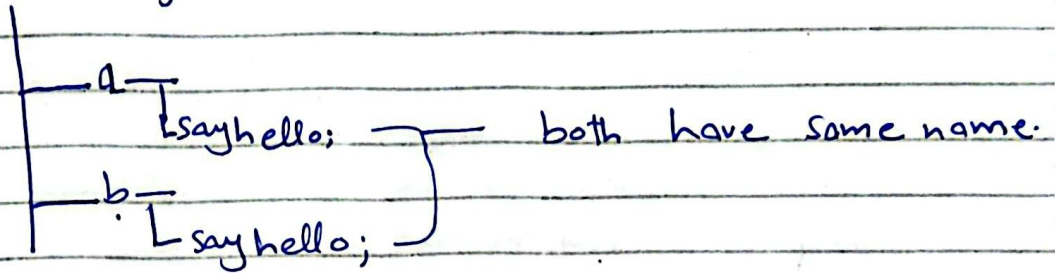

OOP: constructor

inside OOP package there are two
folders.

But in java we cannot make two same name classes in same folder so packages helps us in this

like

Greeting Package

So a concern that name will collide with other classes is gone.

They are stored in hierarchical manner like

in the first line of code we write

package saaim.sayGreeting.sayhello;

first folder

inside saaim folder

inside both of these folders then this folder

saaim

└ sayGreeting

└ sayhello

└ file.

How does java know this:

we can actually import class from another package.

import static com.kunal.packageb.Message.method

↓
class

↓
method

we are
importing.

So how java know is through
import statement.

So at runtime it will look through
import statement. where is the method
we are looking for.

Also if the package (folder) is
same we don't have to import it.
